Transformations of Cartesian tensors (any number of dimensions) Tensors are defined as quantities which transform in a certain way under linear transformations of coordinates. Second order. Let $a = a_i e_i$ and $b = b_i e_i$ be two vectors, so that they transform according to $a_j = a_i L_{ij}$, $b_j = b_i L_{ij}$. Taking the tensor product gives:

A Cartesian tensor of order N , where N is a positive integer, is an entity that may be represented as a set of 3^N real numbers in every Cartesian coordinate system with the property that if $(a_{ijk}...)$ is the representation of the entity in the x_i -system and $(a'_{ijk}...$

For Cartesian tensors we used the fact that the transformation coefficients were elements of orthogonal matrices to show that the result of a contraction was a tensor expression whose rank had been decreased by 2. For our present more general tensors we can still prove that the result of a contraction is a tensor, but the key to the proof is the

Cartesian Tensors 3.1 Summation Convention We will consider vectors in 3D, though the notation we shall introduce applies (mostly) just as well to n dimensions. For a general vector $x = (x_1, x_2, x_3)$ we shall refer to x_i , the i th component of x . The index i may take any of the values 1, 2 or 3, and we refer to “the ...”

Cartesian tensors may be used with any Euclidean space, or more technically, any finite-dimensional vector space over the field of real numbers that has an inner product. There are considerable algebraic simplifications, the matrix transpose is the inverse from the definition of an orthogonal transformation:.

This paper considers certain simple and practically useful properties of Cartesian tensors in three dimensional space which are irreducible under the three dimensional rotation group. Ordinary tensor algebra is emphasized throughout and particular use is made of natural tensors having the least rank consistent with belonging to a particular irreducible representation of the rotation group.

Tensors of rank 0 (scalars) are denoted by means of italic type letters a ; tensors of order 1 (vectors) by means of boldface italic letters \mathbf{a} and tensors of rank two and higher orders by cap-ital boldface letters \mathbf{A} . In some special circumstances, three-dimensional Cartesian coordinates are used: a, a

For more comprehensive overviews on tensor calculus we recom- mend [54, 96, 123, 191, 199, 311, 334]. The calculus of matrices is presented in [40, 111, 340], for example. Section A.1 provides a brief overview of basic alge- braic operations with vectors and second rank tensors. Several rules from tensor analysis are summarized in Sect.

Spherical tensors are apparently a special case of Cartesian tensors (see for example B. Baragiola, unless the pdf is wrong). Perhaps an article on Cartesian tensors including reducibility (like the section in this article, taken from Baragiola) may help these red articles ? (In addition the original intentions stated above).

The set of orthogonal tensors is denoted O_3 ; the set of proper orthogonal transformations (with determinant equal to +1) is the special orthogonal group (it does not include reflections), denoted SO_3 . It holds that $O_3 = \{ \pm R/R \in SO_3 \}$. Theorem. Q is orthogonal iff $(Q.u, Q.v) = (u,v)$, $\forall u, v$, so Q preserves the scalar product between two vectors. ...

Vectors are introduced in terms of cartesian components, making the concepts of gradient, divergent and curl particularly simple. The text is supported by copious examples and progress can be checked by completing the many problems at the end of each section. Answers are provided at the back of the book.
