Programming with threads introduces new difficulties even for
experienced programmers. Concurrent programming has
techniques and pitfalls that do not occur in sequential
programming. Many of the techniques are obvious, but some
are obvious only with hindsight.

A thread is a sequence of such instructions within a program that can be executed independently of other code. The figure to the right conceptually shows that threads are within the same process address space, thus, much of the information present in the memory description of the process can be shared across threads.

1.0 POSIX Threads Synchronization. POSIX Threads provide multiple flows of execution within a process. The threads have their own stacks but share the global data and the heap. So the global variables are visible to multiple threads. Also, the threads need to synchronize their actions so that they jointly realize the overall objectives of the process they belong to.

POSIX Threads Synchronization in C | SoftPrayog

With those clear semantics, the executor is able to dispatch tasks among its internal threads pool by "stealing" jobs when a task is waiting for another task to complete and there are pending tasks to be run. ForkJoinTask objects feature two specific methods: The fork () method allows a ForkJoinTask to be planned for asynchronous execution.

Threads share memory directly. Each thread can read and write variables in shared memory without any overhead. However when threads simultaneously read and write the same data it's called a data race and generally causes problems. In particular, threads in banker.chave data races when they read and write account balances.

Concurrent programming, with examples

Threads are popular way to improve application through parallelism. For example, in a browser, multiple tabs can be different threads. MS word uses multiple threads, one thread to format the text, other thread to process inputs, etc. Threads operate faster than processes due to following reasons:

Multithreading in C - GeeksforGeeks

Threads/ Processes are the mechanism by which you can run multiple code segments at a time, threads appear to run concurrently; the kernel schedules them asynchronously, interrupting each thread from time to time to give others chance to execute.
