screening tests for autoimmune urticaria the latest data on autoimmune mechanisms that initiate chronic urticaria and angioedema in some patients, and abnormalities of signal transduction that may be found in both the autoimmune and "idiopathic" subgroups

Contact urticaria syndrome was first defined in 1975 and since then scientific interest has steadily increased. New cases are continuously being reported furnishing information on novel clinical features. A large number of compounds could be responsible for triggering the syndrome including fragrances, cosmetics, latex, preservatives, flavorings, and disinfectants. However, contact urticaria syndrome is often misdiagnosed in part due to a misinterpretation of its clinical manifestation and lack of knowledge of appropriate testing protocols and diagnostic programs. The latter have to be individualized for each patient based on the substance in question, medical history, possible concomitant disease, and clinical symptoms reported after exposure to the suspected culprit. Contact Urticaria Syndrome explains various aspects of this syndrome. The book discusses its definition, history, epidemiology, and occupational relevance. It also provides a detailed discussion of various triggers including proteins, chemical compounds, agricultural chemicals, metals, plants, foods, and other substances. The book describes known immunological and nonimmunological reactions along with diagnostic tools and test procedures. This comprehensive text is a helpful resource for dermatologists, toxicologists, immunologists, physicians, and other health care providers diagnosing and treating patients with contact urticaria syndrome. It summarizes clinical experience that makes it easier for providers to select the appropriate diagnostic tools and therapeutic approaches.
